Requirement context: Booth member search and person verification

The booth member opens **Your houses**, searches for a household or person, then opens a house to record visit and verification details. The new requirement is to improve how search finds and presents matching houses and people, and to make an individual person's verified details available for printing.

1. Search should handle partial and imperfect input

Search should find relevant results when the user enters only part of a name or voter ID, or makes a small typing error. Matching should be based on characters and similarity, rather than requiring an exact full-text match.

For example, if the stored name is **Ganesh** and the user types **Ganhe**, the person should still appear as a likely match. Voter IDs should also support partial matching; the note's example shows a stored ID like `TT0190561` and a shorter query like `TT161`. The exact normalization and matching rules still need to be defined.

The note also shows `A*` and `E` as a search-pattern example, but the intended meaning of `*` and how that pattern should affect results are unclear. This should be clarified before implementation.

2. Show useful matches as the user searches

As the user types in the search field on the house list, the app should display similar matching results. The handwritten note suggests keeping the result set to fewer than 10 entries, but it does not make clear whether those entries should be **houses**, **people**, or a mix. The result limit and presentation should be confirmed.

The search should fit the existing flow shown in the screenshots: search from **Your houses**, open a matching house, and then review or update the people in that house.

3. Provide a printable record for a verified person

After a particular person has been verified in the house detail screen, the user should be able to print that person's record. The note lists these fields for the printout:

- Name
- Voter ID
- Booth
- Father's name
- Sex

This describes a **per-person print action after verification**, rather than printing a general house list. The final layout and whether any additional visit or verification fields should appear are not specified.

Clarifications needed for a complete specification

- What does the `A* … E` search-pattern example mean?
- Should search results list houses, people, or both?
- Is the intended limit fewer than 10 results, or up to 10?
- How should voter IDs be normalized for partial matching?
- Should the printout include only the listed identity fields, or also verification status and visit details?

This is requirement analysis only; no application changes were made.

Requirement Addendum

These additions supplement the existing requirement analysis. The original two-page document and its existing context are retained unchanged.

4. Select and print multiple records in one action

When matching records are displayed after a search, allow the user to select multiple eligible person records using a visible tick-box selection control, similar to selecting photos in a gallery.

Provide a clear **Print selected** action that prints all selected records together in one bulk print flow. Keep the existing option to print an individual verified person's record. Show which records are selected and the number selected, and let the user deselect records before printing.

Selection applies to the person records shown in the search results; each printed record should follow the existing person-print fields and eligibility requirements.

5. Show father's name clearly on matching search results

For every familiar or similar person record displayed as a search match, show that person's father's name as well.

Present the father's name as a distinct, neatly aligned and visually highlighted detail outside the main result card, so it is easy to notice without crowding or changing the card's existing content. If the imported record has no father's name, use the product's standard unavailable-value treatment.

> **The original requirements, examples, and unresolved clarification points remain as written.**
